## General Description

These monolithic converters are derived from the 256-bit read only memories, DM5488, and DM7488. Emitter connections are made to provide direct read-out of converted codes at outputs Y8 through Y1, as shown in the function tables. These converters demonstrate the versatility of a read only memory in that an unlimited number of reference tables or conversion tables may be built into a system. Both of these converters comprehend that the least significant bits (LSB) of the binary and BCD codes are logically equal, and in each case the LSB bypasses the converter as illustrated in the typical applications. This means that a 6 -bit converter is produced in each case. Both devices are cascadable to N bits.
An overriding enable input is provided on each converter which when taken high inhibits the function, causing all outputs to go high. For this reason, and to minimize power consumption, unused outputs Y 7 and Y 8 of the 185A and all "don't care" conditions of the 184 are programmed high. The outputs are of the open-collector type.

## DM74184 BCD-TO-BINARY CONVERTERS

The 6-bit BCD-to-binary function of the DM74184 is analogous to the algorithm:
a. Shift BCD number right one bit and examine each decade. Subtract three from each 4-bit decade containing a binary value greater than seven.
b. Shift right, examine, and correct after each shift until the least significant decade contains a number smaller than eight and all other converted decades contain zeros.
In addition to BCD-to-binary conversion, the DM74184 is programmed to generate BCD 9's complement or BCD 10's complement. Again, in each case, one bit of the complement code is logically equal to one of the BCD bits; therefore, these complements can be produced on three lines. As outputs Y6, Y7 and Y8 are not required in the BCD-to-binary conversion, they are utilized to provide these complement codes as specified in the function table when the devices are connected as shown.

## DM74185A BINARY-TO-BCD CONVERTERS

The function performed by these 6-bit binary-to-BCD converters is analogous to the algorithm:
a. Examine the three most significant bits. If the sum is greater than four, add three and shift left one bit.
b. Examine each BCD decade. If the sum is greater than four, add three and shift left one bit.
c. Repeat step b until the least-significant binary bit is in the least-significant BCD location.

$\mathrm{H}=$ High Level, $\mathrm{L}=$ Low Level, $\mathrm{X}=$ Don't Care
Note A: Input Conditions other than those shown produce highs at outputs Y1 through Y5.
Note B: Output Y6, Y7, and Y8 are not used for BCD-to-Binary conversion.
Note C: Input conditions other than those shown produce highs at outputs Y6, Y7, and Y8.
Note D: Outputs Y1 through Y5 are not used for BCD 9's or BCD 10's complement conversion.
$\dagger$ When these devices are used as complement converters, input $E$ is used as a mode control. With this input low, the BCD 9's complement is generated; when it is high, the BCD 10's complement is generated.

## LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
